

About

This project showcases data visualization and performance analysis through an interactive Power BI dashboard designed to evaluate portfolio performance and attribution. The dataset includes benchmark index data and portfolio data derived from an investment fund's performance.

Key Components

- Data Processing: Data cleaning and transformation were conducted using Excel and Power Query.
- Calculations & Analysis: Implemented using DAX, including portfolio weight calculations, the Brinson attribution model for performance attribution, and key rate duration (KRD) analysis for fixed-income exposure.
- Dashboard Structure: The dashboard features five key pages:
 1. Summary – Provides an overview of portfolio performance.
 2. Equity Analysis – Performs attribution analysis for equity holdings.
 3. Fixed Income Analysis – Breaks down fixed-income asset performance by sector and risk factors.
 4. Risk Analysis – Assesses portfolio risks using metrics such as volatility, tracking error, and value at risk (VaR).
 5. Scenario Analysis – Examines portfolio performance under various economic conditions.

Limitations & Future Improvements

- Data Constraints: The dataset spans only nine months with monthly data points, limiting certain risk measurements such as volatility trends and drawdown analysis.
- Scope: The dataset includes only Canadian equity and fixed-income assets. Expanding the dataset to include global markets, additional asset classes, and a longer time horizon would enhance the depth and accuracy of the analysis.
